INTRODUCTORY STATISTICS

Shafer and Zhang LibreTexts

1.1: Basic Definitions and Concepts

Learning Objectives

• To learn the basic definitions used in statistics and some of its key concepts.

We begin with a simple example. There are millions of passenger automobiles in the United States. What is their average value? It is obviously impractical to attempt to solve this problem directly by assessing the value of every single car in the country, add up all those values, then divide by the number of values, one for each car. In practice the best we can do would be to *estimate* the average value. A natural way to do so would be to randomly select *some* of the cars, say 200 of them, ascertain the value of each of those cars, and find the average of those 200 values. The set of all those millions of vehicles is called the *population* of interest, and the number attached to each one, its value, is a *measurement*. The average value is a *parameter*: a number that describes a characteristic of the population, in this case monetary worth. The set of 200 cars selected from the population is called a *sample*, and the 200 numbers, the monetary values of the cars we selected, are the *sample data*. The average of the data is called a *statistic*: a number calculated from the sample data. This example illustrates the meaning of the following definitions.

Definitions: populations and samples

A **population** is any specific collection of objects of interest. A **sample** is any subset or subcollection of the population, including the case that the sample consists of the whole population, in which case it is termed a census.

Definitions: measurements and Sample Data

A **measurement** is a number or attribute computed for each member of a population or of a sample. The measurements of sample elements are collectively called the **sample data**.

Definition: parameters

A **parameter** is a number that summarizes some aspect of the population as a whole. A **statistic** is a number computed from the sample data.

Continuing with our example, if the average value of the cars in our sample was \$8,357, then it seems reasonable to conclude that the average value of all cars is about \$8,357. In reasoning this way we have drawn an inference about the *population* based on information obtained from the *sample*. In general, *statistics* is a study of data: describing properties of the data, which is called *descriptive statistics*, and drawing conclusions about a population of interest from information extracted from a sample, which is called *inferential statistics*. Computing the single number \$8,357 to summarize the data was an operation of descriptive statistics; using it to make a statement about the population was an operation of inferential statistics.

Definition: Statistics

Statistics is a collection of methods for collecting, displaying, analyzing, and drawing conclusions from data.

Definition: Descriptive statistics

Descriptive statistics is the branch of statistics that involves organizing, displaying, and describing data.

Definition: Inferential statistics

Inferential statistics is the branch of statistics that involves drawing conclusions about a population based on information contained in a sample taken from that population.

The measurement made on each element of a sample need not be numerical. In the case of automobiles, what is noted about each car could be its color, its make, its body type, and so on. Such data are categorical or qualitative, as opposed to numerical or quantitative data such as value or age. This is a general distinction.

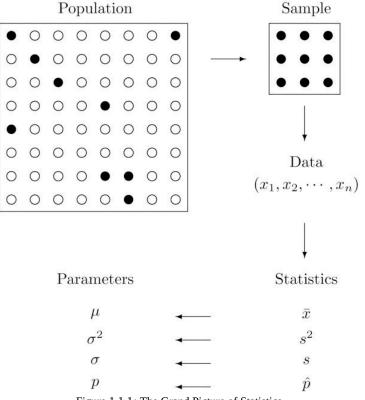

🔗 Definition: Qualitative data

Qualitative data are measurements for which there is no natural numerical scale, but which consist of attributes, labels, or other non-numerical characteristics.

Quantitative data are numerical measurements that arise from a natural numerical scale.

Qualitative data can generate numerical sample statistics. In the automobile example, for instance, we might be interested in the proportion of all cars that are less than six years old. In our same sample of 200 cars we could note for each car whether it is less than six years old or not, which is a qualitative measurement. If 172 cars in the sample are less than six years old, which is 0.86 or 86%, then we would estimate the parameter of interest, the population proportion, to be about the same as the sample statistic, the sample proportion, that is, about 0.86.

The relationship between a population of interest and a sample drawn from that population is perhaps the most important concept in statistics, since everything else rests on it. This relationship is illustrated graphically in Figure 1.1.1. The circles in the large box represent elements of the population. In the figure there was room for only a small number of them but in actual situations, like our automobile example, they could very well number in the millions. The solid black circles represent the elements of the population that are selected at random and that together form the sample. For each element of the sample there is a measurement of interest, denoted by a lower case x (which we have indexed as x_1, \ldots, x_n to tell them apart); these measurements collectively form the sample data set. From the data we may calculate various statistics. To anticipate the notation that will be used later, we might compute the sample mean \bar{x} and the sample proportion \hat{p} , and take them as approximations to the population mean μ (this is the lower case Greek letter mu, the traditional symbol for this parameter) and the population proportion p, respectively. The other symbols in the figure stand for other parameters and statistics that we will encounter.

Key Takeaway

- Statistics is a study of data: describing properties of data (descriptive statistics) and drawing conclusions about a population based on information in a sample (inferential statistics).
- The distinction between a population together with its parameters and a sample together with its statistics is a fundamental concept in inferential statistics.
- Information in a sample is used to make inferences about the population from which the sample was drawn.

1.E: Introduction to Statistics (Exercises)

These are homework exercises to accompany the Textmap created for "Introductory Statistics" by Shafer and Zhang. Complementary General Chemistry question banks can be found for other Textmaps and can be accessed here. In addition to these publicly available questions, access to private problems bank for use in exams and homework is available to faculty only on an individual basis; please contact Delmar Larsen for an account with access permission.

1.1: Basic Definitions and Concepts

Questions

- 1. Explain what is meant by the term *population*.
- 2. Explain what is meant by the term *sample*.
- 3. Explain how a sample differs from a population.
- 4. Explain what is meant by the term sample data.
- 5. Explain what a parameter is.
- 6. Explain what a statistic is.
- 7. Give an example of a population and two different characteristics that may be of interest.
- 8. Describe the difference between *descriptive statistics* and *inferential statistics*. Illustrate with an example.
- 9. Identify each of the following data sets as either a population or a sample:
 - a. The grade point averages (GPAs) of all students at a college.
 - b. The GPAs of a randomly selected group of students on a college campus.
 - c. The ages of the nine Supreme Court Justices of the United States on January 1, 1842
 - d. The gender of every second customer who enters a movie theater.
 - e. The lengths of Atlantic croakers caught on a fishing trip to the beach.
- 10. Identify the following measures as either quantitative or qualitative:
 - a. The 30 high-temperature readings of the last 30 days.
 - b. The scores of 40 students on an English test.
 - c. The blood types of 120 teachers in a middle school.
 - d. The last four digits of social security numbers of all students in a class.
 - e. The numbers on the jerseys of 53 football players on a team.
- 11. Identify the following measures as either quantitative or qualitative:
 - a. The genders of the first 40 newborns in a hospital one year.
 - b. The natural hair color of 20 randomly selected fashion models.
 - c. The ages of 20 randomly selected fashion models.
 - d. The fuel economy in miles per gallon of 20 new cars purchased last month.
 - e. The political affiliation of 500 randomly selected voters.
- 12. A researcher wishes to estimate the average amount spent per person by visitors to a theme park. He takes a random sample of forty visitors and obtains an average of \$28 per person.
 - a. What is the population of interest?
 - b. What is the parameter of interest?
 - c. Based on this sample, do we know the average amount spent per person by visitors to the park? Explain fully.
- 13. A researcher wishes to estimate the average weight of newborns in South America in the last five years. He takes a random sample of 235 newborns and obtains an average of 3.27 kilograms.
 - a. What is the population of interest?
 - b. What is the parameter of interest?
 - c. Based on this sample, do we know the average weight of newborns in South America? Explain fully.
- 14. A researcher wishes to estimate the proportion of all adults who own a cell phone. He takes a random sample of 1,572 adults;
 - 1,298 of them own a cell phone, hence $1298 / 1572 \approx .83$ or about 83% own a cell phone.
 - a. What is the population of interest?
 - b. What is the parameter of interest?
 - c. What is the statistic involved?

- d. Based on this sample, do we know the proportion of all adults who own a cell phone? Explain fully.
- 15. A sociologist wishes to estimate the proportion of all adults in a certain region who have never married. In a random sample of 1,320 adults, 145 have never married, hence $145 / 1320 \approx .11$ or about 11% have never married.
 - a. What is the population of interest?
 - b. What is the parameter of interest?
 - c. What is the statistic involved?
 - d. Based on this sample, do we know the proportion of all adults who have never married? Explain fully.
- 16. a. What must be true of a sample if it is to give a reliable estimate of the value of a particular population parameter?
 - b. What must be true of a sample if it is to give *certain* knowledge of the value of a particular population parameter?

Answers

- 1. A population is the total collection of objects that are of interest in a statistical study.
- 2.
- 3. A sample, being a subset, is typically smaller than the population. In a statistical study, all elements of a sample are available for observation, which is not typically the case for a population.
- 4.
- 5. A parameter is a value describing a characteristic of a population. In a statistical study the value of a parameter is typically unknown.
- 6.
- 7. All currently registered students at a particular college form a population. Two population characteristics of interest could be the average GPA and the proportion of students over 23 years.
- 8.
- 9. a. Population.
 - b. Sample.
 - c. Population.
 - d. Sample.
 - e. Sample.
- 10.
- 11. a. Qualitative.
 - b. Qualitative.
 - c. Quantitative.
 - d. Quantitative.e. Qualitative.
- 12.
- 13. a. All newborn babies in South America in the last five years.
 - b. The average birth weight of all newborn babies in South America in the last five years.
 - c. No, not exactly, but we know the approximate value of the average.
- 14.
- 15. a. All adults in the region.
 - b. The proportion of the adults in the region who have never married.
 - c. The proportion computed from the sample, 0.1.
 - d. No, not exactly, but we know the approximate value of the proportion.

CHAPTER OVERVIEW

2: Descriptive Statistics

Statistics naturally divides into two branches, descriptive statistics and inferential statistics. Our main interest is in inferential statistics to try to infer from the data what the population might thin or to evaluate the probability that an observed difference between groups is a dependable one or one that might have happened by chance in this study. Nevertheless, the starting point for dealing with a collection of data is to organize, display, and summarize it effectively. These are the objectives of descriptive statistics, the topic of this chapter.

- 2.1: Three Popular Data Displays
- 2.2: Measures of Central Location Three Kinds of Averages
- 2.3: Measures of Variability
- 2.4: Relative Position of Data
- 2.5: The Empirical Rule and Chebyshev's Theorem
- 2.E: Descriptive Statistics (Exercises)
